8.3	Update from LinLogBook 0.2 to 0.2.1	11

1 Features

LinLogBook is a highly configurable logbook program. It uses sqlite as sql - database to store its data.

You can export your qso data to a file in adif format for uploading to eqsl or you can directly label your qsl cards.

You can configure LinLogBook by defining some tables and assigning some values during the setup process. For more informations see section 5.

LinLogBook supports two modes

- Enter the qso data manually
- Run LinLogBook as TCP Logbook server

You can import and export the data in adif format.

2 Requirements

LinLogBook was tested with gcc 4.1.2 and uses sqlite as sql- database version 3.x. It requires qt 4.3 or higher.

3 Installation

LinLogBook uses qmake, so the process of building does not use the autoconf tools.

Do the following steps:

- Untar the LinLogBook package
tar xzf LinLog-0.1.2.tar.gz
- Switch to the LinLog directory
- run:
qmake -unix -o Makefile linlog.pro
make
- linlog is build in the bin subdirectory. Move the binary into preferred location , probably /usr/local/bin
- It is recommended that you create a working directory for LinLogBook. For instance create .LinLog in your homedirectory and copy the file BaseTables.sql into this working directory.

Now you can start linlog and choose your personal setup.

4 For the impatient

After the installation start LinLogBook and run linlog.

Select File : new Database and select a name for your database.

Select Edit : Create Basetables

Select the file Example.sql from the LinLog directory.

Select Edit : Define Database Fields and modify the Column LinLogFields and the column DefaultValue depending on your needs and click OK.

Then select Edit : Create QSo tables

Now you are ready to retrieve qso data.

5 Configuration

Start LinLogBook and go to *Edit* menu. Select *Preferences* and fill out the form. The directory entry is relative to your home directory. It is a good idea to choose the same directory where you have put BaseTable.sql.

Select the *File* menu and *create a new database*. Then change to the *Edit* menu and create the basetables. You can use the file BaseTables.sql distributed with LinLogBook or you can adjust the tables to your needs by modifying the file BaseTables.sql.

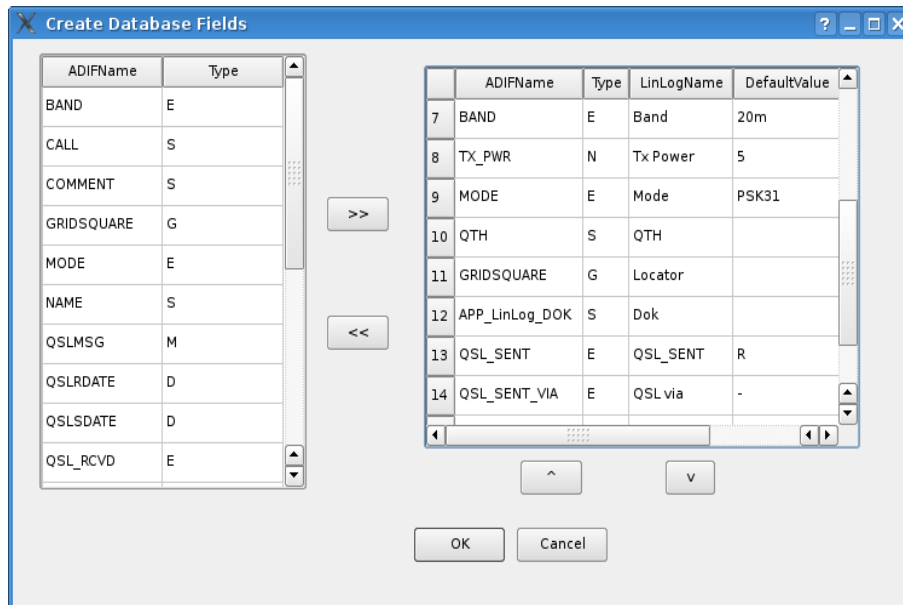

The table ADIF contains the possible entries your logbook could contain. This table consists of the columns ADIFName and Type. The ADIFNames are taken from the ADIF 2 specifications.(<http://www.adif.org/adif218.htm>). You should only use valid adif names, as these names are taken for exporting the data. I put some names into the table that I use within my own logbook. But there are much more possible entries.

LinLogBook uses the following types of the adif specification:

- String labeled S
- Date labeled D (You can choose the preferred date format in the Preferences panel)
- Time (HH:MM) labeled T
- Gridsquare labeled G . This labeling is used to be able to check the formal syntax of the entered values. If exported in adif format it is outputted as string.
- Enumeration labeled E. For each enumeration you must setup an extra table. See section 6
- Number labeled N. At the moment treated as string.
- Multiline string labeled as M. At the moment treated as string.

After the definition of the basetables you can choose the items you wish to use in your logbook.

To do so, select Define Database Fields in the Edit menu and you'll get the following form:

Select the entries you want to use and move them into the right box. Insert an descriptive text in the third column of the right box. This text will be used as an column header in your logbook later on. The columns appear in your logbook in the same order as the appear in the right box. If you want to change the order of your columns , use the up and down arrows beneath the right box. You can change the columns and their order as long as you didn't create the qso table.

You can assign default values to the fields of type 'E' and the type 'N'. You do this by double clicking corresponding field of the column labeled DefaultValue. If you are satisfied with your definitions create the qso table. Again you find this topic in the Edit menu.

Now your logbook is ready to use.

6 Tables for enumerations

For each entry of type enumeration a table containing the posible values must be created. The name of this table must be the name of entry. This table contains two columns. The first is named Id and the second the name of the table followed by value.

The following example is taken from the definition of the enumeration of the band entry:

```
create table BAND (Id INTEGER PRIMARY KEY AUTOINCREMENT,
BANDvalue UNIQUE NOT NULL);
insert into BAND (BANDvalue) values('160m');
insert into BAND (BANDvalue) values('80m');
insert into BAND (BANDvalue) values('60m');
insert into BAND (BANDvalue) values('40m');
insert into BAND (BANDvalue) values('30m');
insert into BAND (BANDvalue) values('20m');
```

```
insert into BAND (BANDvalue) values('17m');
insert into BAND (BANDvalue) values('15m');
insert into BAND (BANDvalue) values('12m');
insert into BAND (BANDvalue) values('10m');
insert into BAND (BANDvalue) values('6m');
insert into BAND (BANDvalue) values('2m');
insert into BAND (BANDvalue) values('70cm');
```

If you'll work other bands, too, you can enter these bands into this table. Otherwise, if you never operate in some of these bands, you can remove these entries. In this way you can configure LinLogBook depending on your needs.

7 Usage

Start LinLogBook. Open your database from the *File* menu. Now you can enter your qso data. To make the logging easier, you can select default values for the band and the mode.

You can search in your logbook for a qso with a special callsign by entering the callsign in the callsign field. If you enter only some initial values all callsigns starting with these values are looked for and the qsos are listed.

7.1 File Menu

Open Database

Here you open an existing database for further processing.

New Database

Here you create a new database. If you select the name of an existing one its contents will be overwritten.

Save Database Definition

You can save the definitions (sql statements) of your logbook as a file. You can use this file to setup a new logbook by executing this file in Edit ⇒ Create basetables .

Hint If you want to modify your logbook, for instance inserting some new columns, save your definitions and export all your qso data as an adif file. Then setup a new, empty database. Use your stored definitions as basetables. Afterwards you can modify your column setup. After creating the new qso table you can restore your qso data by importing the saved adif file. Don't forget to save the views, too.

Save Views

If you have created views - for instance to calculate some statistics - you can save your views to a file, for later use.

Import cty.dat

The cty.dat file contains DXCC entities and is maintained by Jim Reisert, AD1C. See <http://country-files.com> for more information and download. To import the city.dat file just download it and then run *Import cty.dat* from the *File menu*

Import Adif File

You can import adif data from a file into your logbook. Adif fields in your file that are not defined in your logbook will be ignored.

Export Adif File

You can export all of your logged data into one file. So you can save your data.

Export for EQSL upload

If the ADIF field QSL_SENT is used all records having QSL_SENT set to 'R' will be exported to a file. This file could be uploaded to eqsl.cc for instance. While exporting these data the status of the field QSL_SENT is set to yes and if the field QSL_SENT_VIA was added to your database fields it will be set to 'e'.

Print QSL Card

If the ADIF field QSL_SENT is used all records having QSL_SENT set to 'Q' will be printed. You can choose as destination either a printer or a file. Printing to file generates a pdf document. You must define the layout of the print output in the *QSL Card Setup* in the Edit menu. You will be asked if the print was ok. If you say yes, QSL_SENT is set to yes, otherwise the QSL_SENT remains unchanged.

7.2 Edit Menu

Here you find the main tasks to configure the appearance and the characteristics of your personal logbook.

Create Basetables

If you setup a new logbook first you have to define which elements the logbook should possibly contain. This is done by creating the basetables. LinlogBook contains a file **BaseTables.sql** that contains a set of usefull definitions. These definitions are made by sql statements and you can expand them by editing this file. For example you can add adif fields by adding values to the ADIF table. You can also expand or reduce the list of bands and modes you are working by editing this file.

You can create these basetables only once

Define Database Fields

By defining the database fields you select those fields you will actually use in your logbook and you label the columns. You can change this selection up to the final creating of the qso table.

Create QSO Table

Creating the qso table means establishing the logbook. LinLogbook is ready for use. After this step you can't change the definition of this logbook anymore.

Update Basetables

Here you can execute sql statements stored in a file.

Two possible usecases are

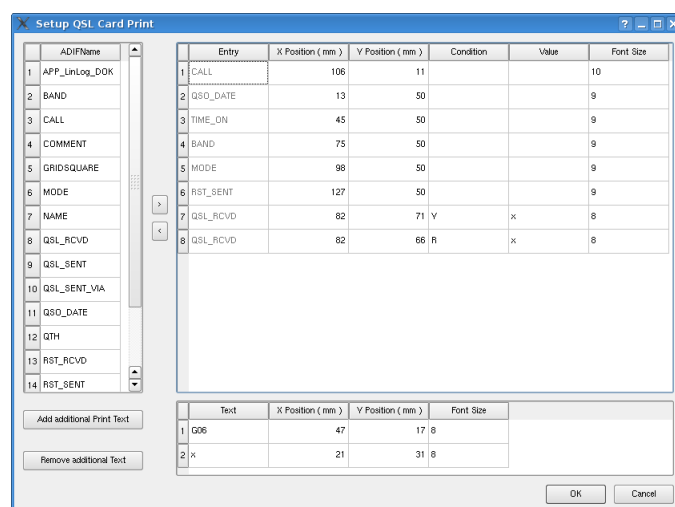

- You want to expand the bands or modes that can be assigned in your logbook. Write the insert statements into a file and choose this file to update your basetables. In the file BaseTables.sql you see the syntax of the appropriate sql statements.
- If you want to expand the features of your logbook by inserting additional columns you did not use up to now, you have to recreate your logbook. First you have to save the database definitions and views to files and store the entered data into another file by exporting them as adif file. Then you can create a new database and load your previous definitions by updating the (at this moment empty) basetables by the stored database definitions.
After this step the qso table is not defined yet, so you can expand your definition by new database fields. If the favoured fields are not in the adif field list, you have to update your ADIF table. For more informations see section 5. If the definition fits your needs, create the qso table and create the views (if necessary) by updating the basetables by running the file you saved your views to.
Now import your saved adif data and your redesigned logbook is ready for use.

QSL Card Setup

Here you define which fields of your logbook will be printed to your qsl card. Additionally you have to define the print position in mm and you can choose a font size between 8 and 12 points.

You are even able to print some text conditionally. I use this to mark either the *TNX QSL* or the *PSE QSL* text on my qsl card.

Here is my setup. Have a look at the two entries of QSL_RCVD.

Preferences

At least the database directory, the date format and the separator should be set. You have to set the port, if you want to be able to run the linlog server. The language selection will not be utilised at the moment and the other fields are for later use, too.

7.3 Statistics

LinLogBook owns a simple interface to define statistics. It uses the sql table *statistics* which has the following definition:

```
create table statistics (MenuText UNIQUE NOT NULL,sql NOT NULL);
```

The first column contains the name of entry in the *Statistics menu*. The second entry contains the corresponding sql statement to calculate the desired statistic. You find two examples in the file **Statistics.sql**. The first example counts the number of confirmed and unconfirmed qsos for each worked band and mode whilst the second example counts the worked and confirmed qsos for each country. This example requires the *cty.dat* file to be imported.

Country	Worked	Confirmed
Argentina	3	1
Asiatic Russia	1	0
Australia	1	0
Austria	5	2
Balearic Is.	1	0
Belgium	6	4
Bulgaria	1	0
Canada	1	0
Croatia	1	1
Czech Republic	4	1
Denmark	1	1

You implement this statistics by running *Update Base Tables* from the *Edit menu*. Select the file *Statistics.sql* for this update. After restarting LinLogBook the statistics are available.

You can implement your own statistics by updating the **statistics** table. Have a look at the **Statistics.sql** file for some explanations.

7.4 Server Mode

Additionally you can run LinLogBook in server mode. To do so select start server in the server menu. A small TCP- server will listen on all interfaces. The port is configurable in *Preferences* in the Edit menu. This feature is intended to be used together with programs for digital modes.

Data have to be sent in adif format on a per line basis. Each adif entry has to be one line. Sending `<eor>` means end of record and leads to storing the received data.

Sending `@@@callsign` requests informations on the callsign. LinLogBook sends back some country information and if the callsign has already been worked.

8 Appendix

8.1 Update from 0.1.1 to 0.1.2

To use the complete functions of LinLog 0.1.2 the database tables have to modified. If you are already using an earlier version of LinLog you can do this the following way

- Install LinLog 0.1.2
- For security reasons copy your database file to a new file
- Run LinLog 0.1.2 and open your database
- Export the database contents using export Adif File in the *File Menu*

- Save the database definition to an file using the corresponding item in the *File Menu*
- Restart LinLog 0.1.2 and create a new database. You may use the same name for your database. In this case the old database will be overwritten.
- Run *Create Basetables* from the *Edit menu*
Choose the file you saved your database definitions to.
- Run *Update Basetables* from the *Edit menu*
Choose the file *updateBaseTables-0.1.1-0.1.2.sql* from the LinLog directory
- Run *Define Database Fields* from the *Edit menu*
Now you can choose default settings for all enumeration types (Band, Mode) and numerical types (TX_POWER) by double clicking into the **DefaultValue** column.
A new ADIF - field **QSL_SENT_VIA** was introduced to the database definitions. If you add this field to the used database fields, you can keep track of eqsl - upload.

8.2 Update to LinLogBook 0.2

To achieve a better representation of the statistics it was inevitable to slightly modify the qso table. To make use of this modification do the following.

- Install LinLog 0.2
- For security reasons copy your database file to a new file
- Run LinLog 0.2 and open your database
- Export the database contents using export Adif File in the *File Menu*
- Save the database definition to an file using the corresponding item in the *File Menu*
- Restart LinLog 0.2 and create a new database. You may use the same name for your database. In this case the old database will be overwritten.
- Run *Create Basetables* from the *Edit menu*
Choose the file you saved your database definitions to.
- Run *Define Database Fields* from the *Edit menu*
At this stage you might change the column names or the default values assigned to some columns.
- Run *Create Qso Table* from the *Edit menu*
- Run *Import Adif File* from the *File menu*

8.3 Update from LinLogBook 0.2 to 0.2.1

The list of qsos will now be ordered by QSO_DATE (, TIME_ON or TIME_OFF). The later depends on the fields you defined in your linlogbook. Due to problems with some features of qt, this requires to create a view.

The easiest way is to modify the file `updateBaseTables-0.2-0.2.1.sql` by removing the % sign in front of the line that fits to your logbook definition. Then run *update BaseTables* from the *edit Menu* and choose this file to run.

If you don't so, you won't see your qso entries when starting LinLogBook 0.2.1. But the entries are not lost. You will see these data again as soon as you run the update script and restarting LinLogBook.
